

In this exercise we consider the second-order system

$$\ddot{x} + k_1\dot{x} + k_2x = k_3u \quad (1)$$

In state-space form, with $x_1 = x$ and $x_2 = \dot{x}$, we get

$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -k_2 & -k_1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + \begin{bmatrix} 0 \\ k_3 \end{bmatrix} u \quad (2)$$

Discretizing the system using the explicit Euler scheme with sampling time T gives

$$\frac{x_{t+1} - x_t}{T} = \begin{bmatrix} 0 & 1 \\ -k_2 & -k_1 \end{bmatrix} x_t + \begin{bmatrix} 0 \\ k_3 \end{bmatrix} u_t \quad (3)$$

and hence

$$x_{t+1} = \underbrace{\begin{bmatrix} 1 & T \\ -k_2T & 1 - k_1T \end{bmatrix}}_A x_t + \underbrace{\begin{bmatrix} 0 \\ k_3T \end{bmatrix}}_B u_t \quad (4)$$

Let $k_1 = k_2 = k_3 = 1$ and $T = 0.1$. The initial condition is $x_0 = [5 \ 1]^\top$; the initial state estimate is $\hat{x}_0 = [6 \ 0]^\top$ when an observer is used.

Problem 1 (20 %) The Riccati Equation

The algebraic or stationary Riccati equation is stated as

$$P = Q + A^\top P(I + BR^{-1}B^\top P)^{-1}A \quad (5)$$

in the MPC note. Another common form of this equation is

$$A^\top PA - P - A^\top PB(R + B^\top PB)^{-1}B^\top PA + Q = 0 \quad (6)$$

(see, e.g., the MATLAB documentation for the `dlqr` function). We use the matrix inversion lemma (also known as the Sherman-Morrison-Woodbury formula)

$$(S + UTV)^{-1} = S^{-1} - S^{-1}U(T^{-1} + VS^{-1}U)^{-1}VS^{-1} \quad (7)$$

to derive (6) from (5).

In order to apply the matrix inversion lemma we need to choose S , T , U , and V . We can then use the lemma to rewrite $(I + BR^{-1}B^\top P)^{-1}$. When we compare

$$(S + UTV)^{-1} \quad \text{and} \quad (I + BR^{-1}B^\top P)^{-1} \quad (8)$$

we immediately see that we have to set $S = I$. In the right-hand side of (7) the inverses of S and T appear, meaning these matrices have to be square. $S = I$ is already chosen (and is square); B is generally not square, but R and P are always square. We can not set T equal to P , since they appear in different places inside the parentheses in (8). A natural choice is then $T = R^{-1}$. It follows that we need to choose $U = B$ and $V = B^\top P$. With these choices, we have

$$\begin{aligned}(S + UTV)^{-1} &= S^{-1} - S^{-1}U(T^{-1} + VS^{-1}U)^{-1}VS^{-1} \\ &= I^{-1} - I^{-1}B(R + B^\top PI^{-1}B)^{-1}B^\top PI^{-1} \\ &= I - B(R + B^\top PB)^{-1}B^\top P\end{aligned}\tag{9}$$

We can now rearrange (5) to

$$A^\top P(I + BR^{-1}B^\top P)^{-1}A - P + Q = 0\tag{10}$$

and then replace $(I + BR^{-1}B^\top P)^{-1}$ by $(I - B(R + B^\top PB)^{-1}B^\top P)$ from (9) and get

$$A^\top P(I - B(R + B^\top PB)^{-1}B^\top P)A - P + Q = 0\tag{11}$$

which we rearrange to

$$A^\top PA - A^\top PB(R + B^\top PB)^{-1}B^\top PA - P + Q = 0\tag{12}$$

which is identical to (6) (except for the position of $-P$).

Problem 2 (30 %) LQR and State Estimation

We will in this problem assume that only x_1 is measured; that is,

$$y_t = Cx_t = \begin{bmatrix} 1 & 0 \end{bmatrix} x_t\tag{13}$$

We use LQR and an observer to control the output.

a We want to minimize the infinite-horizon objective function

$$f^\infty(z) = \frac{1}{2} \sum_{t=0}^{\infty} \{ \hat{x}_{t+1}^\top Q \hat{x}_{t+1} + u_t^\top R u_t \}\tag{14a}$$

with

$$Q = \begin{bmatrix} 4 & 0 \\ 0 & 4 \end{bmatrix} \quad \text{and} \quad R = 1\tag{14b}$$

Note that the objective function is formulated in \hat{x}_{t+1} (the state estimate) as opposed to x_{t+1} (the actual state). The MATLAB script A7prob2a.m published on Blackboard uses the MATLAB function `dlqr` to find the optimal feedback gain K , assuming that the full state is available for feedback. The result is $K = \begin{bmatrix} 1.0373 & 1.6498 \end{bmatrix}$ and closed-loop poles $\lambda = 0.8675 \pm 0.0530j$ (with magnitude $|\lambda| = 0.8691 < 1$).

- b** The MATLAB file A7prob2b.m published on Blackboard uses the function `place` to place the observer poles at $p_{1,2} = 0.5 \pm 0.03j$ in the z -plane. The result is shown in Figure 1 and Figure 2. We see that the state estimates converge fairly rapidly, and that the controller successfully steers the states to the origin. In Figure 1 and Figure 2, different responses due to different eigenvalues for the observer have been plotted. One may see that the slower the observer becomes (i.e., the higher absolute value of the poles), the longer it takes for the system to converge. Another interesting phenomenon is that a slower observer, will lead to a slower change in the controller input, which can be seen in Figure 2. This is reasonable as the estimated state will change slower.
- c** The control and estimation equations can be written

$$\xi_{t+1} = \begin{bmatrix} x_{t+1} \\ \tilde{x}_{t+1} \end{bmatrix} = \underbrace{\begin{bmatrix} A - BK & BK \\ 0 & A - K_F C \end{bmatrix}}_{\Phi} \xi_t \quad (15a)$$

$$\tilde{x}_t = x_t - \hat{x}_t \quad (15b)$$

With the values used above, we have

$$\Phi = \begin{bmatrix} 1.0000 & 0.1000 & 0 & 0 \\ -0.2037 & 0.7350 & 0.1037 & 0.1650 \\ 0 & 0 & 0.1000 & 0.1000 \\ 0 & 0 & -1.6090 & 0.9000 \end{bmatrix} \quad (16)$$

Using MATLAB, we find that the eigenvalues of Φ are $\lambda = 0.8675 \pm 0.0530j$, $0.5 \pm 0.03j$, which we recognize as the eigenvalues of $A - BK$ and $A - K_F C$.

Problem 3 (30 %) MPC and State Estimation

We now add the input constraint

$$-4 \leq u_t \leq 4 \quad t = 1, \dots, N - 1 \quad (17)$$

and use MPC with Q and R as given in (14b).

- a** Figure 3 shows the system response when controlled by an MPC with state estimate feedback. The performance is not as good as what we obtained with LQR, since we use a short prediction horizon and do not hit the input constraints. Increasing the horizon to $N = 40$ gives much better results in this case. The MATLAB file A7prob3a.m published on Blackboard was used to obtain the results.
- b** The MATLAB file A7prob3b.m published on Blackboard controls the system with MPC and full state feedback. The result is shown in Figure 4. The state trajectories are very similar to those obtained in Problem 3a), but we see that the control input is smoother for the first few time steps. This is because we now use the true state for feedback, not the state estimates, which were inaccurate and slightly oscillatory at the beginning of the simulation.

Problem 4 (20 %) Infinite-Horizon MPC

- a** The Riccati matrix P was found with `dlqr` in the MATLAB script `A7prob2a.m`:

$$P = \begin{bmatrix} 27.5170 & 7.2713 \\ 7.2713 & 10.2339 \end{bmatrix} \quad (18)$$

- b** The MATLAB file `A7prob4b.m` published on Blackboard controls the system with state-feedback MPC minimizing the open-loop objective function the open-loop objective function

$$f(z) = \frac{1}{2} \sum_{t=0}^{N-1} \{x_{t+1}^\top Q x_{t+1} + u_t^\top R u_t\} + x_N^\top P x_N \quad (19)$$

Depending on how you implement your MPC, you might have to multiply P by 2 before placing it in the block-diagonal matrix G , see `A7prob4b.m`. The result is shown in Figure 5. See that the states reach the origin faster, and that the control input is at the lower bound for the first few time steps. Decreasing the horizon N has virtually no effect on the closed-loop performance; this is far from true in finite-horizon case (Problem 3b)).

Comparing different poles for the observer - states and estimate
